## REGIONAL AGGREGATION I

Juan Herreño Johannes Wieland

UCSD, Spring 2024

#### **OUTLINE**

- A FEW DIGRESSIONS AND AN EXPERIMENT
- 2 RECAP OF THE AGGREGATE MULTIPLIER
- 3 THE OPEN ECONOMY MULTIPLIER + SUTVA VIOLATIONS
- 4 THE REGIONAL PHILLIPS CURVE
- **5** DEMAND EQUIVALENCE

#### **OUTLINE**

- A FEW DIGRESSIONS AND AN EXPERIMENT
- 2 RECAP OF THE AGGREGATE MULTIPLIER
- 3 THE OPEN ECONOMY MULTIPLIER + SUTVA VIOLATIONS
- 4 THE REGIONAL PHILLIPS CURVE
- **5** DEMAND EQUIVALENCE

#### REPEAT OUR EXPECTATIONS

- We expect you to do a lot of talking
- Try to formulate questions in real time. In class and in seminars
- After each question: What lead this person to ask this? Do you know the answer? Why did not you ask the question before?
- Take notes on other presentations. What worked? What did not work?
- Writing and presenting core to your craft. Take them seriously.
- Every time you present (or hand-out a writeout) your work is being judged, your audience is constantly doing Bayesian updating
- ullet Work in progress eq Mediocre presentation. Work in progress = incomplete but well thought out presentation

#### DIGRESSION 1

- You saw (hopefully) a subset of JMCs giving job talks at UCSD
  - Suhas Vijaykumar coming to UCSD
  - Wendy Morrison to Duke
  - Maren Vairo to Wharton (?)
  - Kevin Dano to Princeton (?)
  - ▶ Benjamin Goldman is going to Cornell

Google their profiles and remember their seminar performance. Their profiles are signals of the 2024 bar to have a shot at jobs like those.

Behind each of those profiles there are huge amounts of work. The substitutability of hard work to other inputs is a well-estimated zero.

#### DIGRESSION 2

• Sometimes incorrect beliefs can be sustained in equilibrium. Examples:

► There are important differences in productivity across researchers, but they have an important endogenous component. Must work hard.

► A good Job market presentation is not the outcome of talent in presenting. Must practice often and meticulously.

▶ Landing most jobs requires work. Not only to have a shot to a Top X job.

#### DIGRESSION 3

- In case it was not obvious. Not all "moments" in the data are equally informative. My favorite example:
- Compute GDP using the income approach  $GDP^I$ , and compute GDP using the expenditure approach  $GDP^X$  in your model and in the data
- Run the same regression in the model as in the data:

$$GDP_t^I = \beta_0 + \beta_1 GDP_t^X + \varepsilon_t$$

- Argue that your model passed the test of rationalizing the data because in the model and in the data you obtain  $\hat{\beta}_1 = 1$ .
- From the perspective of model choice, data moments are useful insofar they partition the set of families of models in a substantive way

# OPEN FLOOR + COLD CALL: PINARDON-TOUATI (2024)

Start in random place and ask these questions sequentially:

- What is the research question?
- ② How does the research question relates to the literature?
- Why is this research question worth asking?
- What data does it use?
- What are the important variables?
- What is the empirical strategy?
- What is the identifying assumption?
- What source of exogenous variation is used in the paper?
- What is the purpose of writing the model?
- What is the main result from the model?

## **OUTLINE**

- A FEW DIGRESSIONS AND AN EXPERIMENT
- 2 RECAP OF THE AGGREGATE MULTIPLIER
- 3 THE OPEN ECONOMY MULTIPLIER + SUTVA VIOLATIONS
- 4 THE REGIONAL PHILLIPS CURVE
- **5** DEMAND EQUIVALENCE

#### OBJECTIVES OF THIS SECTION

We will go over the determinants of the multiplier in closed economy
 Follow Woodford (2011) "simple analytics" paper

Learn to bridge the aggregate and open-economy multipliers
 Use Chodorow-Reich (2019), Nakamura Steinsson (2014), Farhi Werning (2016),
 Pinardon-Touati (2024)

• Core question: Can we learn something from geographic cross-sectional fiscal spending multipliers?

#### OF MULTIPLIERS AND PARAMETERS

Macroeconomists oftentimes interested in two types of objects

- ► Invariant structural parameters (there can be heterogeneity in these)
- ► Elasticities: functions of parameters, prices, equilibrium outcomes

- ullet Caveat: Complicate models: structural parameter o elasticity
- ullet Caveat II: Simplify models: elasticity o structural parameter

## OF MULTIPLIERS AND PARAMETERS

- In our models the expenditure multiplier is **NOT** an structural parameter (not even in the undergraduate AS-AD model we teach in 110B)
- Implications of that: In principle the multiplier depends on:
  - policy reaction (lean against the wind)
  - how expenditures are financed (taxes vs. debt vs. transfers from abroad)
  - real interest rate sensitivities (investment and durable consumption crowding out)
- There is not **ONE** multiplier. Need to be more precise in what you are estimating
- Example: I am estimating the no-monetary policy response, transfer-from-abroad financed spending multiplier

Do not let your audience guessing what you are doing!

Suppose

$$\max_{C_t, H_t} \sum_{t=0}^{\infty} [u(C_t) - v(H_t) + \Gamma(G_t)]$$
$$Y = f(H_t)$$
$$Y_t = C_t + G_t$$

- All prices flexible. All markets competitive
- No capital. No durables. No assets in net supply
- Lump sum taxation
- C, H, and G separable
- ullet What is the effect of increases of  $G_t$  on  $Y_t$

Intratemporal optimization yields (hhs on their labor supply curve)

$$\frac{v'(H_t)}{u'(C_t)} = \frac{W_t}{P_t}$$

Profit maximization yields (firms on their labor demand curve)

$$f'(H_t) = \frac{W_t}{P_t}$$

Combined yield

$$\frac{v'(H_t)}{u'(C_t)} = f'(H_t)$$

## Rearrange

$$\frac{v'(H_t)}{f'(H_t)} = u'(C_t)$$

- RHS: marginal utility of consumption
- LHS: Marginal disutility of producing output.

Use the production function and the resource constraint Y = C + G And the production function Y = f(H)

$$u'(Y_t - G_t) = \tilde{v}'(Y_t)$$

$$u'(Y_t - G_t) = \tilde{v}'(Y_t)$$

Then the multiplier  $\frac{dY}{dG}$  is given by

$$\frac{dY}{dG} = \frac{\eta_u}{\eta_u + \eta_{\tilde{v}}}$$

#### Where

- $\eta_u > 0$  is the negative of the elasticity of u'  $(-\bar{Y}u''/u')$
- $\eta_{\tilde{v}} > 0$  is the elasticity of  $\tilde{v}'$   $(\bar{Y}\tilde{v}''/\tilde{v}')$

That is, the multiplier is between zero and one.

$$\frac{dY}{dG} = \frac{\eta_u}{\eta_u + \eta_{\tilde{v}}}$$

- Multiplier between zero and one
- Government spending "crowds-out" private spending
- Government consumes some stuff
- Households are poorer
- Consume less normal goods (leisure and consumption)
- Multiplier is small iff
  - there is more crowding out
  - Disutility of producing more output rises fast
  - ► Households have large elasticity of intertemporal substitution

• Suppose G is temporarily high today. What happens to the real rate?

$$u'(C_t) = \beta R_t u'(C_{t+1})$$

- There is crowding out,  $R_t$  must be high today. (notional interest rate).
- this interest rate plays a similar role to the one Johannes showed you in computational
- What is the interest rate of a bond (that in eq. is in zero net supply) that would rationalize the sequence of equilibrium consumption

- No mention so far of whether taxes occur today or the future
- Irrelevant! Ricardian equivalence holds in this model
- Depends on lots of assumptions
- What it says: Variation in the timing of lump-sum taxes do not matter for household wealth
- What it does not say: Government spending does not matter for output (it does!)

For you to discuss among you in the break: Is the effect on output today higher or lower in economies where:

- ullet Complementarity in preferences between C and G
- instead of G today there are news of future G
- G is permanent as opposed to transitory
- output is produced with labor and capital
- Instead of G today there are news of future G in a model with capital

- Let's move to the NK model
- No capital. Sticky prices. Flexible wages
- Firms set prices. Commit to meet demand

$$f'(H_t) \neq \frac{W_t}{P_t}$$

- What determines labor demand?
- Product demand!
- Pump up wages since households are on their labor supply schedule
- Not true with sticky wages (modeled in the EHL way at least)

#### Mechanics of the NK model multipliers

- Total demand must hold  $Y_t = C_t + G_t$
- $G_t$  is exogenous
- Dynamics of Y depend on the dynamics of C.
- What determines C?

$$u'(C_t) = \beta R_t u'(C_{t+1})$$

• Key variable: the real interest rate

$$u'(C_t) = \beta R_t u'(C_{t+1})$$

- What determines the real interest rate?
- Monetary policy and price setting behavior
- The response of monetary policy is a crucial determinant of NK multiplier
- Imagine a policy  $R_t = R$
- Then  $C_t = C_{t+1}$ . So  $\frac{dY}{dG} = 1$

$$u'(C_t) = \beta R_t u'(C_{t+1})$$

- Imagine now a Taylor rule
- Fiscal stimulus is inflationary
- Nominal interest rates go up
- Consumption today goes down
- Multiplier is less than one

- What happens in the ZLB?
- G just as inflationary
- nominal interest rates do not react

- real rate decreases
- $\frac{dC}{dG} > 0$ . so  $\frac{dY}{dG} > 1$

## FOR YOU TO THINK IN THE BREAK

• What happens with GHH preferences?

• What happens with hand-to-mouth consumers?

## FARHI AND WERNING (2016)

• Consider a model where  $i_t = \overline{i}$  for  $t \leq T$ , then  $i_t = \overline{r}_t$ 

Suppose the economy goes back to steady state

$$c_t = \int_t^T (i_{t+s} - \pi_{t+s} - \bar{r}_{t+s}) ds$$

• Again: In the NK model g affects c via its effects on the real rate. Not directly.

## FARHI AND WERNING (2016) ON NULL HYPOTHESES

For a sequence of log-deviations  $g_{t+s}$ , can write the solution of the model as

$$egin{aligned} c_t &= ilde{c}_t + \int_0^\infty lpha_s^c g_{t+s} \ \pi_t &= ilde{\pi}_t + \int_0^\infty lpha_s^\pi g_{t+s} \ y_t &= ilde{y}_t + g_t + \int_0^\infty lpha_s^c g_{t+s} \end{aligned}$$

The relevant null hypothesis changes on what you are testing.

- Consumption multipliers equal to zero
- Output multipliers equal to one

#### **SUMMARY**

#### In closed economy:

- ullet In the RBC, the closed economy, lump-sum tax, no capital multiplier  $\in [0,1]$
- Depends on preference elasticities.
- In the NK model: Monetary policy conduct is key.
- $\bullet$  The closed economy, OMP, lump-sum tax, out of the ZLB, no capital multiplier in the NK  $\in [0,1]$
- Can have the same multiplier in both models
- Cannot tell if the world is Keynesian just by looking at this multiplier
- Whether you can actually estimate causal effects of G on Y in the aggregate data is a different issue. Here we wonder about the possibility of rejecting families of models

## **OUTLINE**

- A FEW DIGRESSIONS AND AN EXPERIMENT
- 2 RECAP OF THE AGGREGATE MULTIPLIER
- 3 THE OPEN ECONOMY MULTIPLIER + SUTVA VIOLATIONS
- 4 THE REGIONAL PHILLIPS CURVE
- DEMAND EQUIVALENCE

#### RESULTS FROM THE OPEN ECONOMY MODEL

TABLE 6—GOVERNMENT SPENDING MULTIPLIER IN SEPARABLE PREFERENCES MODEL

	Closed economy aggregate multiplier	Open economy relative multiplier
Panel A. Sticky prices		
Volcker-Greenspan monetary policy	0.20	0.83
Constant real rate	1.00	0.83
Constant nominal rate	$\infty$	0.83
Constant nominal rate ( $\rho_g = 0.85$ )	1.70	0.90
Panel B. Flexible prices		
Constant income tax rates	0.39	0.43
Balanced budget	0.32	0.43

Notes: The table reports the government spending multiplier for output deflated by the regional CPI for the model presented in the text with the separable preferences specification. Panel A presents results for the model with sticky prices, while panel B presents results for the model with flexible prices. The first three rows differ only in the monetary policy being assumed. The fourth row varies the persistence of the government spending shock relative to the baseline parameter values. The fifth and sixth rows differ only in the tax policy being assumed.

Source: Nakamura Steinsson (2014)

#### RESULTS FROM THE OPEN ECONOMY MODEL

TABLE 7-GOVERNMENT SPENDING MULTIPLIER IN GHH MODEL

	Closed economy aggregate multiplier	Open economy relative multiplier
Panel A. Sticky prices		
Volcker-Greenspan monetary policy	0.12	1.42
Constant real rate	7.00	1.42
Constant nominal rate	$\infty$	1.42
Constant nominal rate ( $\rho_g = 0.50$ )	8.73	2.04
Panel B. Flexible prices		
Constant income tax rates	0.00	0.30
Balanced budget	-0.18	0.30

*Notes:* The table reports the government spending multiplier for output deflated by the regional CPI for the model presented in the text with the GHH preferences specification. Panel A presents results for the model with sticky prices, while panel B presents results for the model with flexible prices. The first three rows differ only in the monetary policy being assumed. The fourth row varies the persistence of the government spending shock relative to the baseline parameter values. The fifth and sixth rows differ only in the tax policy being assumed.

Source: Nakamura Steinsson (2014). Question: Why is the multiplier  $= \infty$ 

#### RESULTS FROM THE OPEN ECONOMY MODEL

Table 8—Government Spending Multipliers in Incomplete Markets Model

	Closed economy aggregate multiplier	Open economy relative multiplier
Panel A. Sticky prices		
Baseline model (complete markets)	0.20	0.83
Incomplete markets, locally financed	0.18	0.84
Incomplete markets, federally financed	0.18	0.90
Panel B. Flexible prices		
Baseline model (complete markets)	0.39	0.43
Incomplete markets, locally financed	0.39	0.41
Incomplete markets, federally financed	0.39	0.40

*Notes:* The table reports the government spending multiplier for output deflated by the regional CPI for a version of the model presented in the text with separable utility in which the only financial asset traded across regions is a noncontingent bond. Panel A presents results for the model with sticky prices, while panel B presents results for the model with flexible prices.

Source: Nakamura Steinsson (2014)

# **Q**UESTION

• The open-economy relative multiplier is 2.04 with GHH preferences

• The closed-economy constant-nominal rate multiplier is 8.73

• Both experiments keep rates constant (time-series vs. cross-section)

Why are they not equal?

# QUESTION

How can you have a constant nominal rate policy?

How about Sargent and Wallace?

#### NAKAMURA AND STEINSSON 2014

- The open-economy multiplier is a useful statistic
- Lets us to reject subsets of the model space
- Cannot reject some others. That's how progress looks like.
  - ▶ My thoughts: We learned about the structure of the economy using the geographic cross-sectional multiplier in ways is not possible to do with the aggregate multiplier. In that dimension the cross-regional multiplier is a better moment than the aggregate multiplier.
- It seems however that the answer to the question:
  - What can we learn about the aggregate multiplier when we see the geographic cross-sectional multiplier.
- is "it depends" on what you mean by **the** aggregate multiplier.

#### SUTVA VIOLATIONS: PLEASE BE EXPLICIT

• Replying with "my model includes GE effects" to the question of why you have a model is unsatisfying. Two reasons:

- 1 It is sort of obvious, that is what macro models do
- ② Bypasses the important question: which GE effects are key to include, and why are you including them in the way that you are.

The neoclassical model includes some GE effects, the NK model does to. Which among those should you use? Or a secret third thing?

Are your modeling choices neutral? Why are some GE effects more important than others?

# SUTVA VIOLATION: FINANCING - CHODOROW-REICH (2019)

- Who pays for spending
- In a closed economy, it is always locally-financed
- In an open economy model (OEM), it depends
  - ► Financed locally (taxes vs. deficit)
  - ROW transfer
- OEM with complete markets: completely irrelevant
  - ► For any set of transfers devised by the government, there is an insurance transfer that undoes it.
- With incomplete markets: now we are talking. It matters who pays

Locally financed 
$$\mathcal{M}^G = \text{Transfer-financed } \mathcal{M}^G - \mathcal{M}^T$$

• Remember: we care about Locally financed  $\mathcal{M}^G$  but only observe Transfer-financed  $\mathcal{M}^G$ , so we want to understand how large is  $\mathcal{M}^T$ 

# SUTVA VIOLATIONS: FINANCING

- Foreign transfer financing is the empirically relevant case
   Spending happens locally, but financed at the federal level OEM PF
- How much of the effect happens through the transfer? Size of the transfer is key. Increasing on  $\rho_g$
- Two effects in NK models (you know these from before)
  - SR: sticky prices, transfers increase demand-determined output
    - \* How much in relative terms? Decreasing in openess  $\alpha$ . Less open economies concentrate demand locally
  - In the LR prices adjust, world looks neoclassical. Effects given by wealth effects
    - $\star$  H relatively wealthier, works less. Increasing in elasticity of labor supply  $1/\phi$
  - Mow to weight these effects?
    - $\star$  Parameters that dictate speed of price adjustment. Mainly the slope of the Phillips curve  $\kappa$

# SUTVA VIOLATIONS: FINANCING

- Chodorow-Reich 2019: Illustrative case in the Cole-Obstfeld case  $\sigma = \eta = \gamma = 1$
- In that case:

(7) 
$$\beta_h^{transfer, nominal} V = \left(\frac{1-\alpha}{\alpha}\right) \left(\frac{r}{r+\rho}\right) \Delta G_{s,t},$$

- For  $\alpha = 0.3$ ,  $\rho = 0.8$ , r = 0.03, then  $\beta_h^{transfer,nominal} = 0.07$
- $\bullet$  OEM PF multipliers  $\approx$  1.5. So SUTVA violation is small.
- Nominal expenditure jumps but prices do not. so  $\beta_h^{transfer, nominal} = \beta_h^{transfer, output}$  on impact.
- Going forward: prices adjust, transfer buys less goods. wealth effects impose negative pressure

SUTVA violation less than 0.07

#### SUTVA VIOLATIONS: FINANCING

- Now let's consider deviations from Ricardian Equivalence
  - ► Let's say failure of Ricardian Equivalence comes > 0 share of HtM hh's
- Away from Ricardian Equivalence, the form of local financing matters
  - Higher taxes today
  - 4 Higher debt today
- SUTVA violations are smaller if deficit-financed
- SUTVA violations are larger if tax financed

CR 2019: For non-Ricardian agents, there is an exact analog between having agents in future periods pay for current spending and having agents in other areas pay for current spending.

# SUTVA VIOLATIONS: EXPENDITURE SWITCHING

• The case of financing convered most of this.

• In open regions, increases in local demand create relative price differences

Diminished demand for local varieties

Decreases the value of the OEM

# **SUTVA VIOLATIONS: MIGRATION + INVESTMENT**

Migration pumps up OEM multipliers

• Migration concerns rise with the persistence of spending

Same can be said about K, not only L

SUTVA + external validity concerns

# FINANCIAL CROWDING-OUT: PINARDON-TOUATI (2024)

#### Setting: France over 2006-2018

- 1. Existence: Local government loans crowd out corporate loans
- 2. Quantification:  $\uparrow \in 1$  local government loans  $\Rightarrow \downarrow \in 0.2$  aggregate output
- 3. Determinants: More severe when borrowing from more constrained banks
  - → Mode of financing of government debt matters

$$\underbrace{\Delta C_{fbt}}_{\text{corporate}} = d_{ft} + \beta \underbrace{\Delta C_{bt}^{gov}}_{\text{credit}} + \varepsilon_{fbt}$$

$$\underline{\Delta C_{fbt}}_{\text{corporate}} = d_{ft} + \underline{\beta} \underbrace{\Delta C_{bt}^{gov}}_{\text{credit}} + \varepsilon_{fbt}$$

# Challenge #2: Other shifts in banks' corporate credit supply

- $ightharpoonup \Delta C_{bt}^{gov}$  and  $\Delta C_{fbt}$  simultaneously determined
- $\Rightarrow$  BankExposure<sub>bt</sub> proxy for bank-specific demand for local gvt loans
- (A2) BankExposure orthogonal to other bank-level credit supply shocks

f=firm, b=bank, t=year

$$\Delta C_{fbt} = d_{ft} + \beta BankExposure_{bt} + \varepsilon_{fbt}$$

$$\Delta C_{fbt} = d_{ft} + \beta BankExposure_{bt} + \varepsilon_{fbt}$$

$$\Delta C_{fbt} = d_{ft} + \beta BankExposure_{bt} + \varepsilon_{fbt}$$

Step 1: Estimate 
$$\Delta C_{mbt}^{gov} = \alpha_{mt}^{gov} + \alpha_{bt}^{gov} + \varepsilon_{mbt} \Rightarrow \hat{\alpha}_{mt}^{gov} \approx \text{ "demand-driven" (Amiti Weinstein 2018)}$$

Step 2:  $BankExposure_{bt} = \underbrace{\frac{1}{C_{b,t-1}^{tot}}}_{\text{Normalization}} \times \sum_{m} \underbrace{\frac{C_{bm,t-1}^{gov}}{C_{m,t-1}^{gov}}}_{\text{Market share of bank } b} \times \underbrace{\left[C_{m,t-1}^{gov} \times \hat{\alpha}_{mt}^{gov}\right]}_{\text{ e local gyt loan demand in municipality } m}$ 

$$\Delta C_{fbt} = d_{ft} + \beta BankExposure_{bt} + \varepsilon_{fbt}$$

Step 1: Estimate 
$$\Delta C_{mbt}^{gov} = \alpha_{mt}^{gov} + \alpha_{bt}^{gov} + \varepsilon_{mbt} \Rightarrow \hat{\alpha}_{mt}^{gov} \approx \text{ "demand-driven" (Amiti Weinstein 2018)}$$

Step 2:  $BankExposure_{bt} = \underbrace{\frac{1}{C_{b,t-1}^{tot}}}_{\text{Normalization}} \times \sum_{m} \underbrace{\frac{C_{bm,t-1}^{gov}}{C_{m,t-1}^{gov}}}_{\text{Market share of bank } b} \times \underbrace{\underbrace{[C_{m,t-1}^{gov} \times \hat{\alpha}_{mt}^{gov}]}_{\text{e local gyt loan demand in municipality } m}}_{\text{demand in municipality } m}$ 

$$\Delta C_{fbt} = d_{ft} + \beta BankExposure_{bt} + \varepsilon_{fbt}$$

Step 1: Estimate 
$$\Delta C_{mbt}^{gov} = \alpha_{mt}^{gov} + \alpha_{bt}^{gov} + \varepsilon_{mbt} \Rightarrow \hat{\alpha}_{mt}^{gov} \approx \text{ "demand-driven" (Amiti Weinstein 2018)}$$

Step 2:  $BankExposure_{bt} = \underbrace{\frac{1}{C_{b,t-1}^{tot}}}_{\text{Normalization}} \times \sum_{m} \underbrace{\frac{C_{bm,t-1}^{gov}}{C_{m,t-1}^{gov}}}_{\text{Market share of bank } b} \times \underbrace{\left[C_{m,t-1}^{gov} \times \hat{\alpha}_{mt}^{gov}\right]}_{\text{elocal gyt loan demand in municipality } m}$ 

$$\Delta C_{fbt} = d_{ft} + \beta BankExposure_{bt} + \varepsilon_{fbt}$$

Step 1: Estimate 
$$\Delta C_{mbt}^{gov} = \alpha_{mt}^{gov} + \alpha_{bt}^{gov} + \varepsilon_{mbt} \Rightarrow \hat{\alpha}_{mt}^{gov} \approx \text{ "demand-driven" (Amiti Weinstein 2018)}$$

Step 2:  $BankExposure_{bt} = \underbrace{\frac{1}{C_{b,t-1}^{tot}}}_{\text{Normalization}} \times \sum_{m} \underbrace{\frac{C_{bm,t-1}^{gov}}{C_{m,t-1}^{gov}}}_{\text{Market share of bank } b} \times \underbrace{\underbrace{[C_{m,t-1}^{gov} \times \hat{\alpha}_{mt}^{gov}]}_{\text{elocal gyt loan demand in municipality } m}}_{\text{demand in municipality } m}$ 

$$\Delta C_{fbt} = d_{ft} + \beta BankExposure_{bt} + \varepsilon_{fbt}$$

$$\Delta C_{fbt} = d_{ft} + \beta BankExposure_{bt} + \varepsilon_{fbt}$$

Step 1: Estimate 
$$\Delta C_{mbt}^{gov} = \alpha_{mt}^{gov} + \alpha_{bt}^{gov} + \varepsilon_{mbt} \Rightarrow \hat{\alpha}_{mt}^{gov} \approx \text{"demand-driven" (Amiti Weinstein 2018)}$$

Step 2:  $BankExposure_{bt} = \underbrace{\frac{1}{C_{b,t-1}^{tot}}}_{\text{Normalization}} \times \sum_{m} \underbrace{\frac{C_{bm,t-1}^{gov}}{C_{m,t-1}^{gov}}}_{\text{Market share of bank } b} \times \underbrace{\underbrace{[C_{m,t-1}^{gov} \times \hat{\alpha}_{mt}^{gov}]}_{\text{elocal gvt loan demand in municipality } m}}_{\text{demand in municipality } m}$ 

- Assumption (A2): BankExposure ⊥ bank-level corporate credit supply
  - No sorting on characteristics correlated to both local gvt debt demand and corporate credit supply (Borusyak Hull Jaravel 2021)

$$\Delta C_{fbt} = d_{ft} + \beta BankExposure_{bt} + \varepsilon_{fbt}$$

Step 1: Estimate 
$$\Delta C_{mbt}^{gov} = \alpha_{mt}^{gov} + \alpha_{bt}^{gov} + \varepsilon_{mbt} \Rightarrow \hat{\alpha}_{mt}^{gov} \approx \text{"demand-driven" (Amiti Weinstein 2018)}$$

Step 2:  $BankExposure_{bt} = \underbrace{\frac{1}{C_{b,t-1}^{tot}}}_{\text{Normalization}} \times \sum_{m} \underbrace{\frac{C_{bm,t-1}^{gov}}{C_{m,t-1}^{gov}}}_{\text{Market share of bank } b} \times \underbrace{\underbrace{[C_{m,t-1}^{gov} \times \hat{\alpha}_{mt}^{gov}]}_{\text{elocal gvt loan demand in municipality } m}}_{\text{demand in municipality } m}$ 

- Assumption (A2): BankExposure ⊥ bank-level corporate credit supply
  - ▶ No sorting on characteristics correlated to both local gvt debt demand and corporate credit supply (Borusyak Hull Jaravel 2021)
- Balanced bank covariates
- Shift-share specific tests (Goldsmith-Pinkham Sorkin Swift 2020, Borusyak Hull Jaravel 2021)
  - ▶ 1 Balance municipality-level covariates, 2 Specific exposure shares, 3 Leave-out adjustments More

#### EFFECT ON FIRM×BANK-LEVEL CREDIT

	Credit growth

- 3 THE OPEN ECONOMY MULTIPLIER + SUTVA VIOLATIONS
- 4 THE REGIONAL PHILLIPS CURVE
  - General Points
  - Hurdles in Aggregation

DEMAND EQUIVALENCE

#### **IDENTIFICATION CHALLENGES**

$$\pi_t = \beta E_t \pi_{t+1} - \kappa (u_t - u_t^n) + v_t$$

- Inflation expectations may covary with unemployment
  - ► For example: Imperfectly credible regime change
  - Literature seeks to control for inflation expectations
  - Results sensitive to details / weak instruments (Mavroeidis, Plagborg-Møller and Stock 2014)
- ② Supply shocks  $(u_t^n \text{ and } v_t)$ 
  - ► Lead to positive comovement between inflation and unemployment (stagflation)
  - Good monetary policy compounds the problem by counteracting demand variation, leaving only supply variation (Fitzgerald-Nicolini, 2014, McLeay-Tenreyro 2019)

# THE ROLE OF THE LONG-RUN INFLATION TARGET

$$\pi_t = -\psi \tilde{u}_t + E_t \pi_{t+\infty} + \omega_t$$

- Long-run inflation target major determinant of current inflation
  - Has a coefficient of one
  - ► Current inflation moves one-for-one with beliefs about long-run inflation target
- Inflation can vary without **any** variation in  $\tilde{u}_t$ 
  - Purely due to changes in  $E_t \pi_{t+\infty}$
- Correlation between  $E_t \pi_{t+\infty}$  and  $\tilde{u}_t$  potentially a source of severe omitted variable bias

#### **ADVICE**

- Not writing your models from first principles is really tempting
- In this case, that would amount to take the aggregate PC:

$$\pi_t = \beta E_t \pi_{t+1} - \kappa (u_t - u_t^n) + v_t$$

And just replace t with Ht (H for Home)

$$\pi_{Ht} = \beta E_t \pi_{H,t+1} - \kappa \hat{u}_{Ht} + v_{Ht}$$

- This equation raises conceptual concerns
  - ▶ Permanent deviations from PPP?
  - ▶ What mechanism forces *H* and *F* economies to converge?

### MODEL

- Two regions: Home and Foreign
- Tradeable and non-tradeable sector in each region
- No labor mobility between regions
- Perfect labor mobility between sectors within region
- Monetary union

## HOUSEHOLDS AND FIRMS

- Households:
  - ► Consume and supply labor
  - ▶ Nested CES demand over varieties of traded and non-traded goods
  - GHH preferences
- Firms:
  - ► Linear production function in labor
  - ► Calvo (1983) type price rigidity

#### Model environment

Phillips curve for local non-tradeables

$$\pi_{Ht}^N = \beta E_t \pi_{H,t+1}^N + \lambda \hat{mc}_{Ht}^N$$

- $\lambda$  summarizes price rigidity:  $\lambda = \frac{(1-\alpha)(1-\alpha\beta)}{\alpha}$
- Phillips curve for locally-produced tradeables

$$\pi_{Ht}^T = \beta E_t \pi_{H,t+1}^T + \lambda \hat{mc}_{Ht}^T$$

• Phillips curve for foreign-produced tradeables

$$\pi_{Ft}^T = \beta E_t \pi_{F,t+1}^T + \lambda \, \hat{mc}_{Ft}^T$$

#### MODEL ENVIRONMENT

• In log-linear terms marginal costs are given by (producer-priced) real wages and productivity. For example:

$$\hat{mc}_{Ht}^{N} = \hat{w}_{Ht} - p_{Ht}^{N} - z_{Ht}^{N}$$

And (cpi-deflated) real wages relate to labor

$$\hat{w}_{Ht} - p_{Ht} = \varphi^{-1} \hat{n}_{Ht}$$

So we can express the local-NT Phillips curve as

$$\pi_{Ht}^{N} = \beta E_t \pi_{H,t+1}^{N} + \kappa n_{Ht} - \lambda \hat{p}_{Ht}^{N} + v_{Ht}^{N}$$

#### **OUTLINE**

- A FEW DIGRESSIONS AND AN EXPERIMENT
- 2 RECAP OF THE AGGREGATE MULTIPLIER
- 3 THE OPEN ECONOMY MULTIPLIER + SUTVA VIOLATIONS
- 4 THE REGIONAL PHILLIPS CURVE
  - General Points
  - Hurdles in Aggregation

DEMAND EQUIVALENCE

## AGGREGATE AND REGIONAL PHILLIPS CURVES

• In the aggregate

$$\pi_t = \beta \, \mathsf{E}_t \pi_{t+1} - \kappa \hat{u}_t + \mathsf{v}_t$$

• In a region, for non-tradeables

$$\pi_{Ht}^{N} = \beta E_t \pi_{H,t+1}^{N} - \kappa u_{Ht} - \lambda \hat{\rho}_{Ht}^{N} + v_{Ht}^{N}$$

• Same slope in the model. Extra term.

## RELATIVE PRICE OF NON-TRADEABLES

$$\pi_{Ht}^{N} = \beta E_t \pi_{H,t+1}^{N} + \kappa n_{Ht} - \lambda \hat{p}_{Ht}^{N} + v_{Ht}^{N}$$

- Mechanical reason: labor supply depends on cpi-deflated real wages. marginal cost depends on sectoral-ppi-deflated wages.
- Conceptual reason. Imagine  $\kappa$  is "high"
  - ▶ Imagine a local demand boom  $n_{Ht}$  ↑
  - ▶ Inflation of non-tradeables increases. A lot.
  - More than the price of tradeables
  - Relative prices in the non-traded sector increase
  - Downward pressure on the relative demand for non-tradeables
  - And an non-tradeable inflation as a consequence
  - ► The extra term brings the economy back to PPP

#### IMPORTANCE OF NON-TRADEABLE INFLATION

- Geographic cross-sectional Phillips curve similar to difference in the PC across two regions
- We can compute that object for overall CPI inflation

$$\pi_{Ht} - \pi_{Ft} = \beta E_t(\pi_{H,t+1} - \pi_{F,t+1}) - \phi_N \kappa (n_{Ht} - n_{Ft}) - \lambda \phi_N (\hat{p}_{Ht}^N - \hat{p}_{Ft}^N)$$

- Attenuation bias due to tradeability
- Can think of it as a SUTVA violation
- Higher demand locally spillovers the foreign region
- Focusing on NT inflation solves this particular issue

#### WEALTH EFFECTS

• With separable preferences the aggregate Phillips curve is

$$\pi_t = \beta E_t \pi_{t+1} - \kappa \hat{u}_t + \lambda \sigma^{-1} \hat{c}_t + v_t$$

And the analog for NT goods in the Home region

$$\pi_{Ht}^{N} = \beta E_t \pi_{H,t+1}^{N} - \kappa \hat{u}_{Ht} + \lambda \sigma^{-1} c_{Ht} - \lambda \hat{\rho}_{Ht}^{N} + v_t$$

- However, in the aggregate  $\hat{c}_t = \hat{y}_t = \hat{n}_t + \hat{z}_t = -\hat{u}_t + \hat{z}_t$
- ullet Aggregate PC in terms of u with a slope  $ilde{\kappa}=\lambda(arphi+\sigma^{-1})$
- Not true for local PC  $\hat{y}_{Ht} = -\hat{u}_{Ht} + \hat{z}_{Ht} = \hat{c}_{Ht} + \hat{n}\hat{x}_{Ht}$ , where nx are net exports.
- In general the two slopes will not be the same

## POSSIBLE EXTENSIONS

## One example among many

- The assumption of integrated labor markets is important
- Imagine they are not, and there is a demand boom in the tradeable sector at the local level
- u<sub>Ht</sub> would go down
- But marginal costs in the non-tradeable sector would not react
- ullet Slope for non-tradeables would be small, regardless of aggregate  $\kappa$

## **BIG PICTURE**

• In a standard textbook model  $\kappa_H^N = \kappa$ 

• In more general settings this may not be true

ullet But can still write a model, and set  $(\kappa,\Theta)$  such that the model recovers  $\kappa_H^N$ 

## PHILLIPS CURVE SLOPE

- Choice that seems to be a plain specification choice
  - Aggregate: slope when using one-year ahead inflation expectations

$$\pi_t = \beta \, \mathsf{E}_t \pi_{t+1} - \kappa \hat{u}_t + \mathsf{v}_t$$

Cross-sectional: slope when using time and region fixed effects

$$\pi_{Ht} = -\psi \hat{u}_{jt} + \alpha_t - \gamma_j + \xi_{jt}$$

- $\hat{\kappa} < \hat{\psi}$
- The natural outcome of a conceptual difference in these equations

#### ESTIMATION OF $\kappa$

Take our Phillips curve and iterate it forward

$$\pi_{it}^{N} = \alpha_i + \gamma_t - \kappa E_t \sum_{j=0}^{\infty} \beta^j u_{i,t+j} - \lambda E_t \sum_{j=0}^{\infty} \beta^j \hat{\rho}_{i,t+j}^{N} + \omega_{it}$$

 Replace expectations with realized values and expectation error and truncate the infinite sums:

$$\pi_{it}^N = lpha_i + \gamma_t - \kappa \sum_{j=0}^T eta^j u_{i,t+j} - \lambda \sum_{j=0}^T eta^j \hat{
ho}_{i,t+j}^N + \omega_{it} + \eta_{it}$$

where  $\eta_{it}$  is an expectations error (and truncation error)

- ullet We can now estimate  $\kappa$  using an IV regression
- Calibrate  $\beta = 0.99$

#### ILLUSTRATIVE EXAMPLE

$$\pi_{it}^{N} = \alpha_i + \gamma_t - \kappa E_t \sum_{j=0}^{\infty} \beta^j u_{i,t+j} - \lambda E_t \sum_{j=0}^{\infty} \beta^j \hat{\rho}_{i,t+j}^{N} + \omega_{it}$$

• Assume that u and  $\hat{p}^N$  follow AR(1) processes

$$\pi_{it}^N = lpha_i + \gamma_t - \psi u_{it} - \delta \hat{
ho}_{i,t}^N + \omega_{it}$$

- where for example  $\psi = \kappa/(1-\beta\rho_u)$
- ullet Since eta is close to 1, and unemployment is highly persistent, then  $\psi$  can be substantially larger than  $\kappa$

#### **IDENTIFICATION**

#### Two Approaches:

- Use lagged unemployment and relative prices as instruments
  - Unemployment may reflect supply shocks
  - Time fixed effects capture national supply shocks
  - ▶ Identifying assumption: No relative change in restaurant technology in Texas vs. Illinois when Texas experiences a recession relative to Illinois
- Tradeable demand instrument

### TRADEABLE DEMAND SPILLOVER INSTRUMENT

Tradable Demand<sub>i,t</sub> = 
$$\sum_{x \in T} \bar{S}_{x,i} \times \Delta \log S_{-i,x,t}$$

- $\bar{S}_{x,i}$ : Average employment share of industry x in state i over time
- $\log S_{-i,x,t}$ : National employment share of industry x at time t
- Identifying assumption: supply shocks not simultaneously correlated with **both** shifts  $\Delta \log S_{-i,x,t}$  and shares  $\bar{S}_{x,i}$
- Intuition:
  - Oil boom increases labor demand and wages in Texas
  - "Demand shock" for Texan restaurants
  - ▶ Oil boom does not differentially affect production technology for restaurants in Texas

SCATTERPLOTS—Non-Tradeable Inflation and Unemployment

#### AGGREGATE IMPLICATION

Plot RHS and LHS of

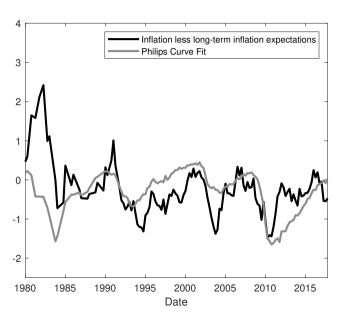

$$\pi_t - E_t \pi_{t+\infty} = -\kappa \zeta \, \tilde{u}_t + \omega_t$$

assuming no supply shocks  $\omega_t = 0$ 

• Scaling factor:  $\zeta = 6.16$  (s.e. 1.80)

$$\sum_{j=0}^{T} \beta^{j} \tilde{u}_{t+j} = \zeta \tilde{u}_{t} + \alpha + \varepsilon_{t}.$$

- Aggregate includes housing
  - Estimate aggregate Phillips curve for shelter
  - Data from American Community Survey for 2001-2017
  - $\kappa = 0.0243$  (s.e. 0.0053) Table
  - About four time larger than for non-shelter

## **OUTLINE**

- A FEW DIGRESSIONS AND AN EXPERIMENT
- 2 RECAP OF THE AGGREGATE MULTIPLIER
- 3 THE OPEN ECONOMY MULTIPLIER + SUTVA VIOLATIONS
- 4 THE REGIONAL PHILLIPS CURVE
- 5 DEMAND EQUIVALENCE

#### **WOLF 2021**

- Remember the Keynesian Cross
  - ► External validity question: Can we learn about shocks to *C* if we knew IRF to responses to *G*?
  - ► The undergraduate version of the paper:

$$Y_t = C_t + G_t$$

$$C_t = a_0 + mpcY_t$$

► Therefore:

$$Y_t = a_0 + mpcY_t + G_t$$

$$Y_t = \frac{a_0}{1 - mpc} + \frac{G_t}{1 - mpc}$$

► So these two multipliers are equivalent for output:

$$\frac{dY}{da_0} = \frac{dY}{dG_t} = \frac{1}{1 - mpc}$$

## **WOLF 2021**

$$\frac{dY}{da_0} = \frac{dY}{dG_t} = \frac{1}{1 - mpc}$$

- Perhaps too simplistic? Does it hold in models where:
  - there are dynamics
  - where households plan consumption paths
  - mpc is not a parameter
  - wealth effects?
  - distortionary taxation?
  - o prices are not fixed?
  - there is investment?
- This paper: Find conditions for a more general result. When is it that shocks to private demand and shocks to public demand disturb the system of market clearing conditions in the same way?

#### PE AND GE RESPONSES

• sh is the sequence of the aggregate state for households

$$\mathbf{s^h} = (\mathbf{i^b}, \pi, \mathbf{w}, \mathbf{l}, au^\mathbf{e}, \mathbf{d}, \mathbf{p^c})$$

- $\varepsilon$  is a sequence of shocks  $\varepsilon \in g, \tau$
- The consumption function is  $\mathbf{c}_{\varepsilon} = \mathbf{c}(\mathbf{s}^{\mathsf{h}}, \varepsilon)$
- ullet The total impulse response of consumption to a shock arepsilon

$$\mathbf{\hat{c}}_{arepsilon} = \mathbf{c}(\mathbf{s^h}, arepsilon) - \mathbf{c}(\mathbf{ar{s}^h}, \mathbf{0})$$

• The direct (PE) response is:

$$\hat{\mathbf{c}}_{\varepsilon}^{\mathsf{PE}} = \mathbf{c}(\mathbf{\bar{s}}^{\mathsf{h}}, \varepsilon) - \mathbf{c}(\mathbf{\bar{s}}^{\mathsf{h}}, \mathbf{0})$$

• The indirect (GE) response is

$$\boldsymbol{\hat{c}}_{\epsilon}^{GE} = \boldsymbol{c}(\boldsymbol{s}^{h}, \boldsymbol{0}) - \boldsymbol{c}(\boldsymbol{\bar{s}}^{h}, \boldsymbol{0})$$

• Can you verbalize what situation would get you each of these effects?

#### PE AND GE RESPONSES

Easy to see that

$$\mathbf{\hat{c}}_{arepsilon} = \mathbf{\hat{c}}_{arepsilon}^{\mathsf{GE}} + \mathbf{\hat{c}}_{arepsilon}^{\mathsf{PE}}$$

- Then under three assumptions
  - Mouseholds and Government consume the same final good
  - 4 Households and Government face the same interest rates
  - No wealth effects on labor supply, or wages are fixed.
- for a fiscal spending policy that satisfies
  - **①** Same net excess demand  $\hat{g}_g = \hat{c}_{\tau}^{PE}$
  - ② Identical endogenous tax responses  $\hat{ au}_g^e = \hat{ au}_{ au}^e$

$$\mathbf{\hat{c}}_{ au} = \mathbf{\hat{c}}_{ au}^{\mathsf{PE}} + \mathbf{\hat{c}}_{\mathbf{g}}^{\mathsf{GE}}$$

#### **INTERPRETATION**

#### DEMAND EQUIVALENCE ILLUSTRATION, STICKY-WAGE HANK MODEL

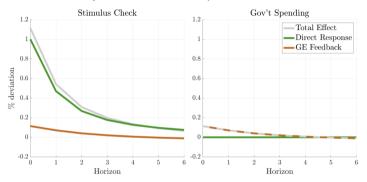

Figure 1: Consumption impulse response decompositions after stimulus check and government spending shocks in the estimated HANK model of Section 4.1, but with fully rigid wages. The direct response and the indirect general equilibrium feedback are computed following Definition 1.

• Question: Why is the Direct response in the right panel = 0?

#### **INTERPRETATION**

- Any two shocks that perturb every market clearing condition in the same way will yield the same GE response
- ullet The assumptions in the method are sufficient to guarantee that for G and T shocks
- Examples of violations:
  - ► The supply curve of airplanes and restaurant meals have different slopes. *G* buys airplanes, households buy meals with their checks.
  - If stimulus checks cause a great resignation, the market clearing condition for L will be perturbed differently by T and G.

#### MAIN CHALLENGES

• It requires that you can estimate the fiscal multiplier on aggregate data.

ullet Matching requirement. The path of g and au may generate the same demand paths

• Question: Why is it that if aggregate multipliers are close to 1, then the missing intercept is close to 0?

# CONVINCING?
